Normal, Alabama**

# Objective

**Develop and test a Neural-Network based model for disaggregating low-resolution satellite microwave measurements to higher resolutions of land surface models, i.e. estimate the 'correct' high (model)-resolution soil moisture pattern using lower-resolution remote observations and ancillary data**

# Approach

## How do we train and validate a disaggregation model?

### *What is ground truth?*

- *In situ* ground truth soil moisture **observations are very limited** in spatial and temporal coverage, limiting our ability to train a neural network.
- Aircraft brightness temperature or emissivity measurements must be converted to soil moisture using an inverse model, adding uncertainty to the estimates. These data are also limited in space and time.
- The most viable approach seems to be to **train a neural network using solely model soil moisture estimates**, then test its performance using actual remotely-sensed data.
- In this approach, model-simulated data serve as a proxy for microwave measurements obtained from aircraft or satellite-borne sensors.

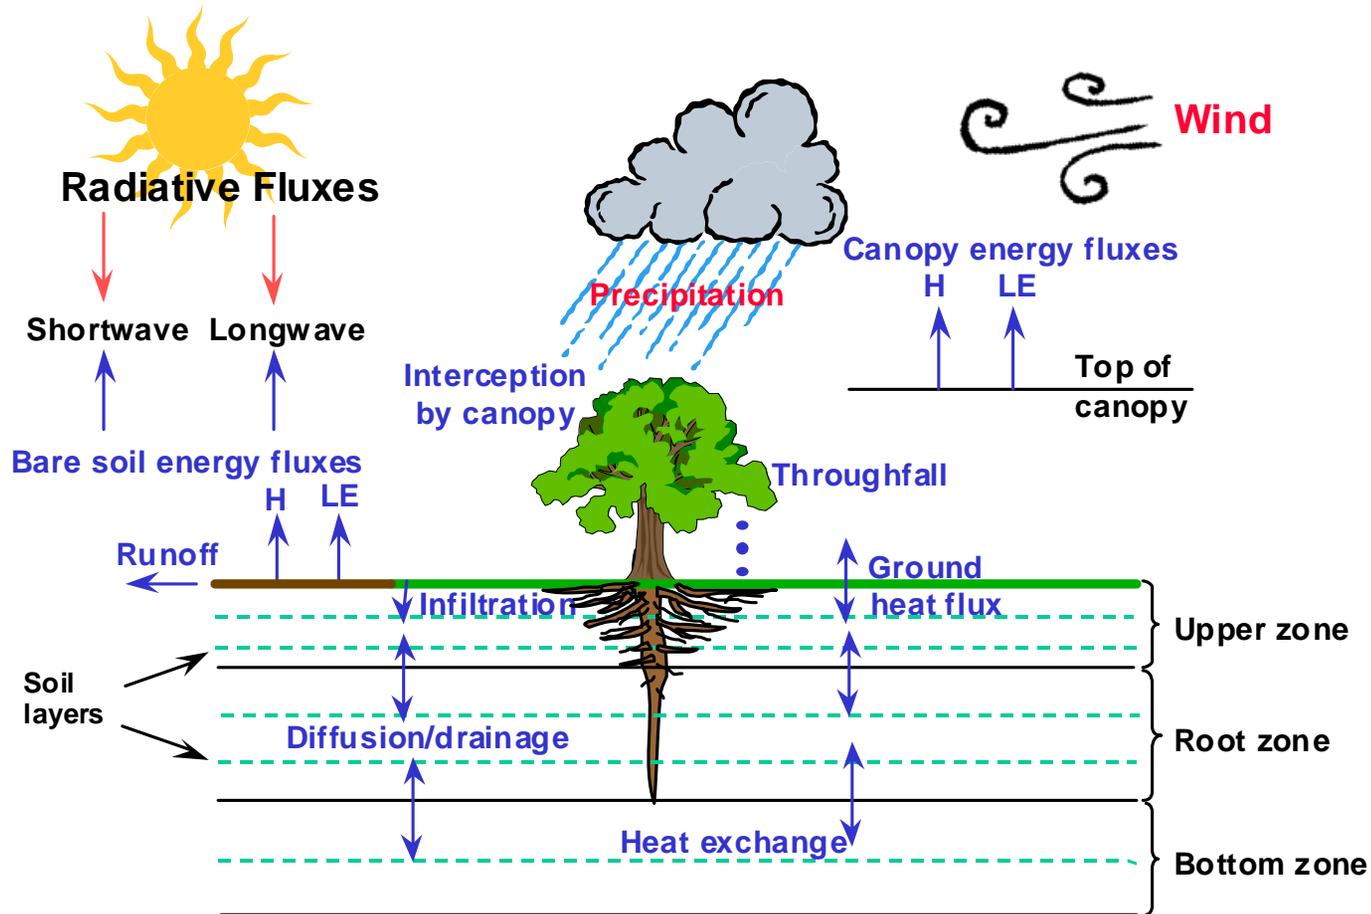

# Assumptions

**Our approach necessitates the following assumptions:**

- 1. The surface hydrology-radiative transfer model accurately simulates spatial patterns of soil moisture and brightness temperature within an actual or hypothetical satellite footprint, although the footprint mean may be biased with respect to the ground truth.**
- 2. Low-resolution brightness temperature observations are unbiased with respect to the ground truth.**
- 3. The functional relationship between brightness temperature and soil moisture 'learned' by the neural network is consistent with the relationship simulated by the radiative transfer model.**

# SHEELS - Simulator for Hydrology and Energy Exchange at the Land Surface

- Accommodates any number of soil layers
- Explicit diffusion schemes for sub-surface moisture and heat fluxes
- Simulates overland runoff
- Linked to radiative transfer model to estimate microwave  $T_B$  and emissivity

# Model study area and data sets

**Model domain -- Little Washita River Basin, OK (600 km<sup>2</sup>)**

**Model grid spacing -- 800 m**

**Terrain slope -- USDA/ARS 30 m DEM, aggregated to 800**

**Hydrography -- USGS DLG's**

**Vegetation parameters -- SGP'97 30 m Land Cover, aggregated to 800 m**

**Soil properties -- CONUS 1 km multi-layer soil characteristics data set, resampled to 800 m**

**L band T<sub>B</sub> -- SGP'97 ESTAR**

**Surface roughness**

**Soil moisture**

**Soil bulk density**

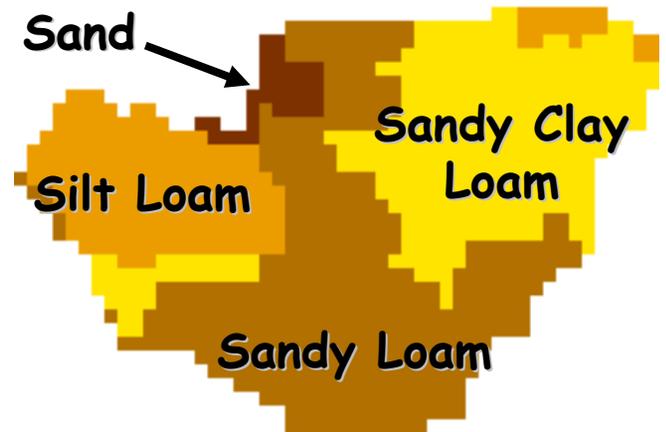

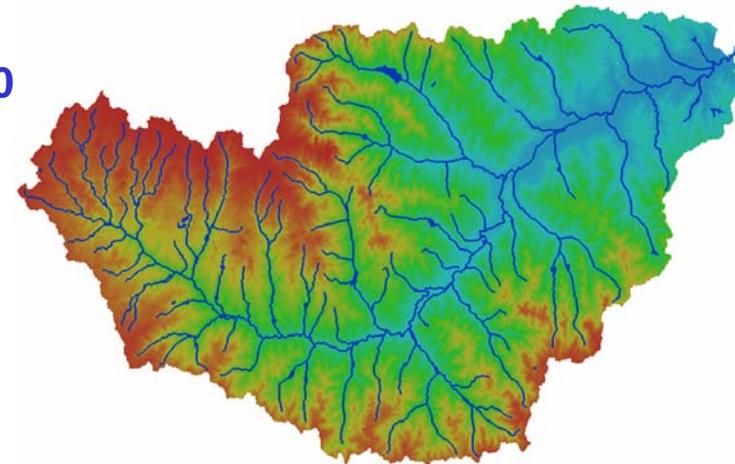

**Percent sand**

**Percent clay**

**Vegetation water content**

**Vegetation b parameter**

**ESTAR-associated data sets**

**Meteorological data -- Oklahoma Mesonet, USDA/ARS Micronet, SGP'97 soil profile stations**

**Precipitation-- USDA Micronet rain gage network, gridded at 800 m using Thiessen polygons**

# Disaggregation Neural Network (DisaggNet)

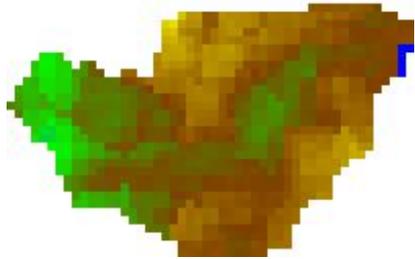

## Design:

- Linear Artificial Neural Network
- Consists of a single neuron

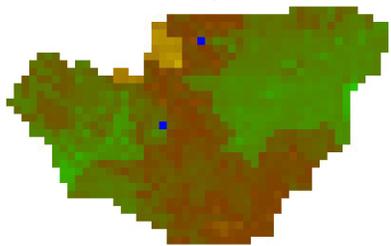

## Training and applying using SHEELS-RTM output:

- Hourly data for 15 consecutive days used
- Wide range of soil moisture conditions
- Use model-estimated L-band emissivity, aggregated to various resolutions, as proxy for remotely-sensed data
- Neural network obtained through training applied to entire 33-day period with Gaussian noise added to emissivity inputs
- Noise has a standard error in emissivity of 0.02, equivalent to ~ 6 Kelvins in  $T_B$  or ~ 2% volumetric water content
- Validate with respect to SHEELS high-resolution soil moisture

**SHEELS high-resolution  
(800 m) soil moisture**

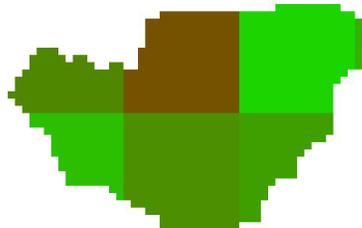

**Apply  
Radiative  
Transfer  
Model**

**SHEELS high-  
resolution emissivity**

**Aggregate,  
add noise**

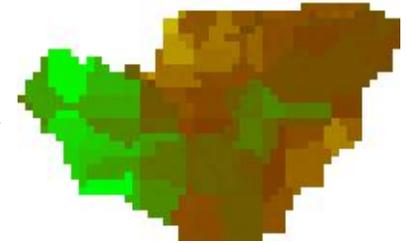

**SHEELS low-  
resolution emissivity**

**Validate vs. SHEELS high-  
resolution soil moisture**

**DisaggNet-estimated high  
resolution soil moisture**

**DisaggNet**

**Inputs (high resolution):**  
Antecedent precipitation  
Sand and clay contents  
Vegetation water content  
Upstream contributing area

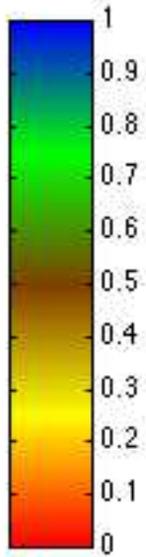

# DisaggNet vs. SHEELS soil moisture estimates 1.6 km and 12.8 km emissivity inputs

DisaggNet 1.6 km

DisaggNet 12.8 km

# DisaggNet vs. ESTAR fractional water content

RMSE for each ESTAR overpass and for each resolution

# DisaggNet vs. ESTAR fractional water content

Time-averaged RMSE based on ESTAR emissivity inputs averaged over the indicated number of pixels

# Conclusions

- DisaggNet was trained using input data simulated by a surface hydrology-radiative transfer model.
- DisaggNet is capable of reproducing sub-pixel-scale soil moisture patterns from low-resolution remote sensing measurements, plus inputs of antecedent precipitation and vegetation, soil and topographic properties.
- Using model-simulated data, RMS errors in fractional water content were approximately 0.05, much of which is attributable to the noise added to the input emissivities.
- RMS errors increase only slightly as input resolution decreases.
- Once trained, DisaggNet was applied to L-band ESTAR emissivity measurements.
- RMS errors using ESTAR inputs are similar to errors obtained using model-simulated data.
- We plan to make the rainfall-soil moisture relationships non-linear, which may improve the performance under very wet conditions.
